

★ = knee, the smallest budget within 2% of the 8192-SPU limit, labelled with its SPU count. Every α we care about places its knee beyond what L40S can build (192 SPU): at 100 μ s it wants 3072, 16 $\times$ the card. B200 reaches its knee within the card for $\alpha \geq 10$ ms but not below. Area is PIM logic only, not the DRAM it sits in.
